

Dequeue. A double-ended queue or deque (pronounced "deck") is a generalization of a stack and a queue that supports adding and removing items from either the front or the back of the data structure. Create a generic data type Deque that implements the following API:

```
public class Deque<Item> implements Iterable<Item> {
    // construct an empty deque
public Deque()
     public boolean isEmpty()
          eturn the number of items on the deque
    public int size()
    public void addFirst(Item item)
     public void addLast(Item item)
               and return the item from the front
    public Item removeFirst()
     // remove and return the item from the back
public Item removeLast()
    // return an iterator over items in order from front to back
public Iterator<Item> iterator()
     public static void main(String[] args)
}
```

Corner cases. Throw the specified exception for the following corner cases:

- Throw an IllegalArgumentException if the client calls either addFirst() or addLast() with a null argument.
- Throw a java.util.NoSuchElementException if the client calls either removeFirst() or removeLast when the deque is empty.
- Throw a java util NoSuchElementException if the client calls the next() method in the iterator when there are no more items to return.
- Throw an UnsupportedOperationException if the client calls the remove() method in the iterator.

Unit testing. Your main() method must call directly every public constructor and method to help verify that they work as prescribed (e.g., by printing results to standard output).

Performance requirements. Your deque implementation must support each deque operation (including construction) in constant worst-case time. A deque containing n items must use at most 48n + 192 bytes of memory. Additionally, your iterator implementation must support each operation (including construction) in constant worst-case time.

Randomized queue. A randomized queue is similar to a stack or queue, except that the item removed is chosen uniformly at random among items in the data structure. Create a generic data type RandomizedQueue that implements the following API:

```
public class RandomizedQueue<Item> implements Iterable<Item> {
         nstruct an empty randomized queue
    public RandomizedOueue()
                            eue empty?
    public boolean isEmpty()
                     mber of items on the randomized queue
    public int size()
    public void enqueue(Item item)
          nove and return a random item
    public Item dequeue()
                        item (but do not remove it)
    public Item sample()
                      pendent iterator over items in random order
    public Iterator<Item> iterator()
    public static void main(String[] args)
}
```

Iterator. Each iterator must return the items in uniformly random order. The order of two or more iterators to the same randomized queue must be mutually independent; each iterator must maintain its own

Corner cases. Throw the specified exception for the following corner cases:

- Throw an IllegalArgumentException if the client calls enqueue() with a null argument.
- Throw a java.util.NoSuchElementException if the client calls either sample() or dequeue() when the randomized queue is empty.
- Throw a java.util.NoSuchElementException if the client calls the next() method in the iterator when there are no more items to return.
- Throw an UnsupportedOperationException if the client calls the remove() method in the iterator.

Unit testing. Your main() method must call directly every public constructor and method to verify that they work as prescribed (e.g., by printing results to standard output).

Performance requirements. Your randomized queue implementation must support each randomized queue operation (besides creating an iterator) in constant amortized time. That is, any intermixed sequence of m randomized queue operations (starting from an empty queue) must take at most cm steps in the worst case, for some constant c. A randomized queue containing n items must use at most 48n + 192 bytes of memory. Additionally, your iterator implementation must support operations next() and hasNext() in constant worst-case time; and construction in linear time; you may (and will need to) use a linear amount of extra memory per iterator.

Client. Write a client program Permutation. java that takes an integer k as a command-line argument; reads a sequence of strings from standard input using StdIn. readString(); and prints exactly k of them, uniformly at random. Print each item from the sequence at most once.

```
~/Desktop/queues> cat distinct.txt
A B C D E F G H I
                                                                                                       ~/Desktop/queues> cat duplicates.txt
AA BB BB BB BB BB CC CC
```

```
A BB CC BB CC BB
```

Your program must implement the following API:

```
public class Permutation {
  public static void main(String[] args)
}
```

Command-line argument. You may assume that  $0 \le k \le n$ , where n is the number of string on standard input. Note that you are not given n.

Performance requirements. The running time of Permutation must be linear in the size of the input. You may use only a constant amount of memory plus either one Deque or RandomizedQueue object of maximum size at most n. (For an extra challenge and a small amount of extra credit, use only one Deque or RandomizedQueue object of maximum size at most k.)

Web submission. Submit a .zip file containing only RandomizedQueue.java, Deque.java, and Permutation.java. Your submission may not call library functions except those in <a href="StdOut">StdOut</a> \$. StdOut</a> \$. StdRandom</a> \$. In particular, do not use either <a href="java.util.linkedList">java.util.linkedList</a> \$. or <a href="java.util.linkedList">java.util.link
